# OBJECT ORIENTED PROGRAMMING WITH JAVA

## Java Applet Programming - I

**Debasis Samanta**

Department of Computer Science & Engineering  
Indian Institute of Technology Kharagpur

# What is an applet?

Java programs are available in two flavors.

## Applet

- A **Java applet** is a program that appears embedded in a web document and applet come into effect when the browser browse the web page.

## Application

- It is similar to all other kind of programs like in C, C++, Pascal, etc. to solve a problem.

IIT KHARAGPUR

# Building an applet

**Edit → Save → Compile**

- Edit the code in the same fashion as an application.
- The name of the applet will be same as the public class, defining the applet, for example, here

`HelloWorld.java`

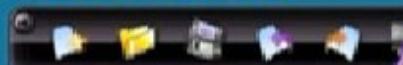

IIT KHARAGPUR

NPTEL ONLINE  
CERTIFICATION COURSES

DEBASIS SAMANTA

IIT KHARAGPUR

# Building an applet

**Edit → Save → Compile**

The program can be compiled in the same fashion as a Java application is compiled. That is,

```
javac HelloWorld.java
```

# Hosting an applet with HTML

```
<html>
  <body>
    <applet width="300" height="300" codebase=". " code="HelloWorld.class">
    </applet>
  </body>
</html>
```

- Write this program using any editor, for example, Notepad, Wordpad, etc.
- Save this to file giving a file name `HelloJava.html`  
Note: The name of the file is not necessarily be the same as the name of the class; but extension should be `.html`
- Now, the applet is ready for its execution!

# Application versus applet

- Applets **do not use main()** method for initiating the execution of code. Applets, when loaded, automatically call certain methods of **Applet class** to start and execute the code in applets
- Unlike application (stand alone), applets **cannot be run independently**. They are to be **embedded in HTML pages** as applet code, which browser can run
- Applet **cannot read from or write to the file** in the local computers
- Applet **cannot communicate with other servers** in the networks
- Applet **cannot run any program** from local computers
- Applets are **restricted from using libraries** from other languages, such as, C, C++, etc.

The screenshot shows a computer monitor displaying a web browser with multiple tabs open. The main content is a profile page for Debasis Samanta. At the top, there is a navigation bar with links for Biography, Research, Publications, Courses, Projects, Students, and Others. Below the navigation bar, there is a large image of an open book. On the pages of the book, three book covers are displayed: "Classic Data Structures" by Debasis Samanta, "OBJECT-ORIENTED PROGRAMMING WITH C++ AND JAVA" by D. SAMANTA, and "MULTIMODAL AND MULTIMODAL BIOMETRIC DATA INDEXING". Each book cover has a "View Details" button below it. Below the book image, there is a section titled "Research & Development" with three cards: "Multimodal Interaction", "SE Visual Lab", and "Text Entry System". The "Multimodal Interaction" card describes a system for accessing information in Indian languages. The "SE Visual Lab" card describes a virtual lab for Software Engineering experiments. The "Text Entry System" card describes a system for entering text in Indian languages on digital devices. The bottom of the screen shows the Windows taskbar with various icons and the date/time as JUN 23 2010 20:22:08.

# Applet concept

- All applets are sub-class of **Applet** (defined in `java.applet` package in JDK. Hence, all applets must **import** `java.applet.*` package.
- Also, all applets must **import** `java.awt` package. AWT stands for *Abstract Window Toolkit*. As applets run in a window, so it is necessary to support for that.
- Applets **are not executed** by console-based Java runtime interpreter.
- In fact, applets **are executed** by a web browser (such as, Hot Java, Netscape Navigator, Internet Explorer 4.0, etc.)
- Also, applets can be executed by the standard executable program called **appletviewer** provided by Java<sup>TM</sup> SDK.

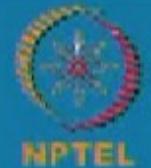

# Execution of an applet

Execution of an applet is controlled with entirely different mechanism.

- As such, there is no `main()` method in an applet program, hence applet does not begin at `main()`.
- Output of an applet is not performed using `System.out.print()` function. Rather, it is handled with various AWT methods, such as `drawString()`, which outputs a string to a specified (x, y) coordinates.
- Input is also handled differently than a normal Java application.

IIT KHARAGPUR

NPTEL ONLINE  
CERTIFICATION COURSES

DEBASIS SAMANTA

IIT KHARAGPUR

# Applet window

An applet is a **window-based** program.

- So called normal, console-based programs, we call them as application (also called Java core programs) are different than applets.
- As in window programs, applets are **event driven**. An applet waits until an event occurs. The AWT notifies the applet about an event by calling an event handler that has been provided by the applet. Once this happens, the applet must take appropriate action and then quickly return control to the AWT.
- Here, an event execution implies **the start of a thread**.
- User should initiate interaction with an applet. It is unlike a non-windowed program, where program prompts for an input, then read it and execute (either in single or multiple threads).

# Applet events

- In applets, events are triggered by a key space, mouse click, mouse drag, etc.
- More precisely, applet contains various controls, such as buttons, text fields, checkboxes, labels, scroll bars, etc.
- User can interact with these controls to generate events.

Import Statements

```
import java.applet.*;
import java.awt.*;
```

init() method

```
public class <APPLET-NAME> extends Applet{
    public void init(){
        //Code for applet initialization.
    }
```

start() method

```
    public void start(){
        //This method is called after init()
        //Also called whenever applet is restarted.
        //This method contains code to start or resume execution.
    }
```

stop() method

```
    public void stop(){
        //This method is called when the applet is stopped.
        //This method contains code to suspend the execution of applet.
    }
```

paint() method

```
    public void paint(){
        //This method contains code to paint the window of an applet.
    }
```

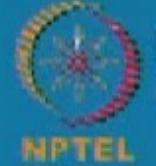

destroy() method

```
    public void destroy(){
        //This method is called when the applet is terminated.
        // This is the last method in the execution of an applet.
        /*
        This method includes the code to perform shutdown activities.
        Usually, the codes are the methods defined in:
        java.awt package
        */
    }
}

# Order of invocation of Applet methods

- These are abstract methods defined in abstract class **Applet** and they need to be overridden in applet programs. It is important to note the order in which the various methods are called.
  
- When an applet begins, the AWT calls the method in the sequence  
**init()** → **start()** → **paint()**
  
- When an applet is terminated, the following sequence of methods call takes place  
**stop()** → **destroy()**
  
- **Note:** All these methods are optional.

# Applet initialization and start : Methods

The **init()** method is the first method to be called. This is where you should initialize an applet. This method **is called only once** during the run time of your applet.

**init()**

**start()**

The **start()** method is called after **init()**. It is also called to restart an applet after it has been stopped. Whereas **init()** is called once—the first time an applet is loaded—**start()** is called **each time an applet's HTML document is displayed onscreen**. So, if a user leaves a web page and comes back, the applet resumes execution at **start()**.

# Applet paint method

## paint()

The **paint()** method is called each time the applet's output to be redrawn. This situation can occur for several reasons. For example, the window in which the applet is running may be overwritten by another window and then uncovered. Or the applet window may be minimized and then restored. **paint()** is also called when the applet begins execution. Whatever the cause, whenever the applet must redraw its output, **paint()** is called. The **paint()** method has one parameter of type **Graphics**. This parameter will contain the graphics context, which describes the graphics environment in which the applet is running. This context is used whenever output to the applet is required.

# Applet termination : Methods

**stop()**

The **stop()** method is called when a web browser leaves the HTML document containing the applet—when it goes to another page, for example. When **stop()** is called, the applet is probably running. You should use **stop()** to suspend threads that do not need to run when the applet is not visible. One can restart them when **stop()** is called if the user returns to the page.

**destroy()**

The **destroy()** method is called when the environment determines that your applet needs to be removed completely from memory. At this point, you should free up any resources the applet may be using. The **stop()** method is always called before **destroy()**.

# Use of destroy(): An example

```
import java.applet.Applet;
import java.awt.Graphics;

public class AppletLifecycle extends Applet{
    StringBuffer strBuffer;
    public void init() {
        strBuffer = new StringBuffer();
        addItem("initializing the applet ");
    }
    public void start() {
        addItem("starting the applet ");
    }
    public void stop() {
        addItem("stopping the applet ");
    }
    public void destroy() {
        addItem("unloading the applet");
    }
}
```

```
void addItem(String word) {
    System.out.println(word);
    strBuffer.append(word);
    repaint();
}
public void paint(Graphics g) {
    // Draw a Rectangle around the applet's display area.
    g.drawRect(0, 0,getWidth() - 1,getHeight() - 1);
    // display the string inside the rectangle.
    g.drawString(strBuffer.toString(), 10, 20);
}
//<applet code="AppletLifecycle.class" width="300" height="200"></applet>
```

# Use of destroy(): An example

```
import java.applet.Applet;
import java.awt.Graphics;

public class AppletLifecycle extends Applet{
    StringBuffer strBuffer;
    public void init() {
        strBuffer = new StringBuffer();
        addItem("initializing the applet ");
    }
    public void start() {
        addItem("starting the applet ");
    }
    public void stop() {
        addItem("stopping the applet ");
    }
    public void destroy() {
        addItem("unloading the applet ");
    }
}
```

```
void addItem(String word) {
    System.out.println(word);
    strBuffer.append(word);
    repaint();
}
public void paint(Graphics g) {
    // Draw a Rectangle around the applet's display area.
    g.drawRect(0, 0,getWidth() - 1,getHeight() - 1);
    // the rectangle.
    g.drawString("Applet Lifecycle", 10, 20);
}

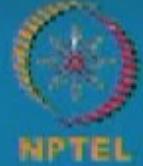

<applet code="AppletLifecycle.java" width="300" height="200"></applet>
```

# Applet update() Methods

- The **update()** method is defined in Applet class. By default, it fills an applet with default background color and then calls **paint()** method.
- Programmer can override the **update()** method, so that it performs all the intended activities, then in **paint()** to call **update()**.

```
public void update(Graphics g) {  
    setBackground(Color.black);  
    setForeground(Color.white);  
    g.drawString("I am from update", 30, 40);  
    // redisplay your window, here.  
}
```

```
public void paint(Graphics g) {  
    update(g);  
    g.drawString("I am from paint", 35, 40);  
}
```

# Applet repaint() method

- Typically, an applet writes to its window using **update()** or **paint()**.
- **Note:** One cannot create a loop in **paint()** to change the information content in an applet.
- Using the **repaint()** method this can be done.
- The **repaint()** causes the AWT runtime system to execute a call to your applet's **update()**, which in turn calls **paint()**.

# Applet repaint() methods

This version causes the entire window to be repainted and is the simplest version

```
void repaint( ) {...}
```

This version specifies a region that will be repainted

```
void repaint(int left, int top, int width, int height) {...};
```

# Applet repaint() Methods

```
void repaint(long maxDelay);
```

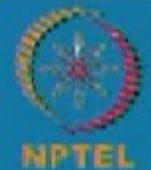

Here, **maxDelay** specifies the maximum number of milliseconds that can elapse before **update()** is called.

```
void repaint(long maxDelay, int x, int y, int width, int height);
```

Note: If the time elapses before **update()** can be called, it isn't called. There's no return value or exception thrown, so you must be careful.
